Question 13:
Both the hand calculation and the code give 0.4601 because they do the exact same math. It uses Variable Elimination, which calculates the exact same sums and divides by the exact same total.

Question 14:
Train is the only parent of Appointment. Since the train is delayed, the appointment doesn't depend on rain or maintenance anymore. We just read 0.4 directly from the table.

Question 16:
Missing the appointment makes it much more likely that the train was delayed. And since train delays are caused by bad weather like heavy rain, that higher delay probability f make heavy rain more likely too.

Question 18:

Heavy rain already makes a delay likely (50% without maintenance and 60% with it), so a delay gives us little extra reason to think maintenance was involved.
